Provide the required program or source code of the given scenario.

1. You've been assigned by your manager to join the coding team responsible for completing the development of the Farm Services Website. This online platform offers various services for farm owners. Your role, as a PHP developer, primarily involves building the business database and finalizing the coding for the designated pages. Follow the instructions provided to construct the system:

   a. The business maintains a database named "**dbFarm**" with one table named "**tblservices**".
      - Create the table "**tblservices** "with the following structure:

Fieldname	**Type and Size**	**Constraint**	**Description**
sid	Int (6)	Primary key, auto Inc	Service ID
fname	Varchar (40)	Not Null	Farm Owner Name
phone	Int (8)	Not Null	Phone Number
size	Int (4)	Not Null	Farm Size
stype	Varchar (40)	Not Null	Service Type
fdis	Varchar (30)	Not Null	Farm Distance
sco	Double (7,3)	Not Null	Service Cost
tco	Double (7,3)	Not Null	Total Cost

   b. Open ***"insert_service.php"*** file where the user enters the **farm owner name**, **phone number, farm size, service type, and farm distance.** Apply the following tasks:

      - In the action attribute of the form, the same file is used for the form and the process.

- Create a sticky form that retains the farm owner name, and service type values even after data submission.
- In the process part, ensure that the user clicks the ***submit*** button.
- Establish connection with the database.
- Apply the required validation to ensure the phone number, and farm size fields are not left blank.
- Initiate a session and save the farm owner's name and the service type in the session.
- Set the base rate as a constant value. The base rate is defined as 0.2.
- Calculate the service cost using the following equation:

  Service cost= base rate* farm size
- The ***tCost*** function takes the service cost and service type as parameters. It performs the following tasks:
  - Calculate the price using the ***associative array***.

Service Type	Price (OMR)
Harvesting	99.75
Planting	127.88
Watering	110.99

  - Compute the total cost using the following equation:

    Total cost =service cost + price
- Save the inputs from the form elements with service cost and total cost to the database table, prepare the query and run it.
- Display a confirmation message for a successful insertion in the database.
- Provide a link to the homepage.

- Display the following details:

c. Open the *"view_services.php"* file, to allow the user to access and view services details.
   - The page will display information on the following:
     - Farm Owner Name,
     - Farm Size,
     - Service Type,

    - Farm Distance, and
    - Delete
- Initiate a session and display the saved session variables above the table.
- Connect to the database.
- Extract and show the required fields ordered by “service type”.
- Provide a link to delete service details.
- Provide a link to the homepage.

d. Open the "delete_service.php" page to allow the user to delete service details. The page performs the following tasks:
   - Connect to the database.
   - Save the URL data to scalar variable.
   - Write a query to delete the required record from the database and run the query.
   - Display confirmation message for a successful deletion from the database.
   - Provide a link for the view services page.

e. Run the application and insert the following sample records.

fname	phone	size	stype	fdis
said	99887766	300	Planting	Less Than 10
salim	99665544	450	Watering	More Than 10

f. Export the database.
